Abstract

Choanal polyps are benign, solitary unilateral soft tissue lesions of sinonasal tract of unclear etiology, usually originate from maxillary sinus mucosa but in some reported cases it can originate from unusual sites. In the present report, we describe an extremely rare case of choanal polyp arising from uncinate process (uncinochoanal) in 22 year female managed in our department. The aim of this report is to highlight an unusual form of choanal polyp.

Keywords: Choanal polyp, uncinate process, uncinochoanal

Introduction

Choanal polyp (CP) was described by Professor Gustav Killian, in 1906. Choanal polyps are unilateral sinonasal lesions that are classified according to their site of origin. Usually arise from the maxillary sinus and extend toward the nasopharynx. In the review of literature, Choanal polyps can originate from unusual locations such as the sphenoid sinus, ethmoid sinus, nasal septum, inferior turbinate, middle turbinate and soft or hard palate as a rare entity. To our best knowledge, no case of uncinochoanal polyp had been reported. Choanal polyps are mostly seen unilaterally, but rare cases of bilateral cases have been reported in the literature.

The exact aetiology of choanal polyps is unknown. It is more commonly seen in young age patients. When a young patient is presenting with complaints of unilateral nasal obstruction or hawking sensation we should have a high suspicion about Sinonasal polyposis. Diagnostic nasal endoscopy (DNE) and radiological study should be carried out followed by endoscopic sinus surgery forms the protocol of management for choanal polyps.

Case report

A 22 year old female presented with right sided nasal obstruction for about 6 months duration. The condition had become progressively worse over time, no nasal discharge, no facial pain and no smell abnormalities. Medical history was unremarkable. Endoscopic nasal examination revealed right side grayish polypoidal mass based in the postero- inferior aspect of the uncinate process with a thin pedicle and the polyp was hanging loosely through the choana. The remaining of the otorhinolaryngologic examination did not reveal any abnormalities.

Figure 2: The polyp filling the right choana
A choanal polyp arising from the uncinate process is extremely rare and not reported in literature. In our case, CP is originating from postero-inferior portion of uncinate process. Although varying in location, CPs present with same symptoms and histological findings as in our case, the most common symptom is nasal obstruction.\(^{(3)}\)\(^{(4)}\)

The differential diagnosis of CP should include angiofibroma, haemangiomia, lymphoma, retention cyst, mucocele, mucopyocele, inverted papilloma, turbinate hypertrophy, adenoid hypertrophy, Turcotte-Landry’s cyst and olfactory neuroblastoma. In particular, inverted papilloma should be considered if there is an unusual site of origin of a CP.\(^{(8)}\)

Endoscopic sinus surgery is recommended treatment and provides low recurrence rate 3.

**Conclusion**

Choanal polyps can arise from unusual locations and should be kept in mind in the diagnosis and management of unilateral nasal obstruction.
